

How to Use the Memory Card Game

To play the Memory Card Game, run the `memory_game.py` program in a Python environment that supports *Tkinter*. The program will display a 4×4 grid of cards, each represented by a button. Initially, all cards are hidden. Click a card to reveal its word, then click a second card to try to find its matching pair.

- If the two cards match, they remain visible and are marked as matched.
- If they do not match, both cards are temporarily displayed before being hidden again.
- Continue selecting pairs until all matches are found.

The program tracks the number of moves and time elapsed. Once all pairs are matched, a prompt appears allowing the player to save their score to `scores.csv`. The game can be restarted at any time by closing and reopening the program.

Note: Ensure that `cards.txt` is present in the same directory as the program to load the card words correctly.
